

Gold ORB V2: what the deals show

Four exported MT5 reports | 2020-01-01 to 2026-09-09 | Prepared for Abhishek

Decision: continue development and forward validation. Carry 0.25 and 0.65 ATR as the two main candidates, retain 0.50 as a comparison, and deprioritize 0.40. These files still do not justify an automatic move to live trading at 1% risk.

The direct exports materially strengthen the analysis: all four runs have the same 1,697 entry timestamps, directions and filled prices, and their only different saved input is the stop multiplier. Every trade and ending balance reconciles. The comparison now isolates stop behavior and its position-sizing consequences much more cleanly than screenshots did.

Candidate	Main result	Main limitation
0.25 ATR	45.93% historical CAGR; PF 1.333; highest budget-R expectancy.	33.57% reported relative equity DD; 552-day balance recovery episode.
0.65 ATR	18.79% CAGR; 13.11% reported equity DD; smallest 2023 loss.	425-day longest balance recovery; lower return and no immunity to adverse regimes.
0.50 ATR	21.37% CAGR; 18.77% reported equity DD.	503-day longest recovery; keep as a middle comparison.
0.40 ATR	24.95% CAGR; positive full-history result.	31.11% reported equity DD; 670-day longest recovery makes the compromise unattractive.

Four findings that change the discussion

- 1. Costs need verification:** every commission and swap entry is zero. Spread/price effects may already be in fills, but these reports do not establish live cost realism.
- 2. Performance is not just a recent fluke:** each variant was profitable over 2020-2022 and over the combined 2020-2023 period. Nevertheless, all four lost money in 2023.
- 3. Recovery can take well over a year:** a tolerable drawdown depth can still mean a long period below your prior account peak.
- 4. These are highly related variants:** daily-return correlations are 0.817-0.955, not independent portfolio systems.

All dollar amounts are USD. CAGR is calculated across 2,443 calendar days (6.6886 years). 2026 results are partial through the final deals on 8 September. This report analyzes the exported historical runs; it does not rerun MT5 or independently verify the underlying market feed.

Data audit and reconstruction

Evidence now available: settings, orders, execution deals and closed balances

Check	Result
Files / settings	ORBGold_025, ORBGOLD_40, ORBGOLD_050, ORBGOLD_065; actual inputs confirm 0.25 / 0.40 / 0.50 / 0.65.
Shared setup	ORB_V2; XAUUSD; USD 10,000; leverage 1:100; broker clock; 03:05-06:05 range; 18:55 close; 1% balance risk.
ATR / entries	D1 ATR(14) stop reference; M5 signal ATR; touch entries; ATR_Buffer_Mult=0.05; no entry cutoff; both range filters off.
Reconstruction	Each: 3,394 trading deals -> 1,697 completed trades, plus one initial balance deposit. No unmatched or overlapping positions.
Reconciliation	Net profit, gross positive/negative P&L; and final balance agree with MT5 to cents. Every deal-level balance movement reconciles.
Matched experiment	All 1,697 entry times, sides and entry fill prices agree exactly across runs. Only Stop_ATR_Mult differs in saved inputs.
Holding / closure	All positions exit on their entry calendar date. Every exit is either SL-commented or at 18:55. No open position remains at the end.

An important classification discrepancy

The short opened on **11 July 2022 at 10:03:35** closes at 18:55 for exactly zero P&L; in all four exports. MT5 includes that trade in its displayed non-losing/profit count. This review counts it separately as breakeven. Consequently strictly positive win rates are about 0.06 percentage points lower than the MT5 headline, without any P&L; discrepancy.

ATR	Positive wins	Losses	Breakevens	Strict win %
0.25	662	1034	1	39.01%
0.40	799	897	1	47.08%
0.50	845	851	1	49.79%
0.65	879	817	1	51.80%

Orders provide initial SL values through the entry order ticket. The files contain no position ID, so linking uses the verified one-open-position state, matching symbol, side, volume and chronology. Orders and deals are not added together as separate trades. The opening deposit and final totals row are excluded from trading P&L.;

The report Period says M15; Signal_Timeframe=5 separately specifies M5. Both can be correct. The 99% history-quality value is reported, not independent proof of real-tick modeling, realistic slippage or a fully representative broker feed.

Return and risk comparison

Independent return calculations; reported equity drawdown remains a separate measure

ATR	Net profit USD	CAGR	PF	Mean budget-R	Equity DD*
0.25	115,274.47	45.93%	1.333	0.163	33.57%
0.40	34,353.46	24.95%	1.237	0.095	31.11%
0.50	26,532.67	21.37%	1.248	0.081	18.77%
0.65	21,635.79	18.79%	1.272	0.071	13.11%

* MT5-reported worst relative equity drawdown. Budget-R = trade P&L; / (1% of balance immediately before entry). It is a risk-budget-normalized outcome, not exact stop-based R.

ATR	Computed daily Sharpe	MT5 Sharpe	Annual daily-return volatility	Balance Calmar*
0.25	1.51	2.50	26.49%	1.39
0.40	1.27	1.96	18.26%	0.82
0.50	1.33	2.00	14.95%	1.20
0.65	1.49	2.20	11.65%	1.57

The daily Sharpe uses Monday-Friday closed-balance returns, including no-trade weekdays, zero risk-free rate and sqrt(252) annualization. It is deliberately reported separately from MT5's statistic. For 0.25, this gives **1.51 rather than 2.50**; differing return sampling/definitions must not be hidden.

* Balance Calmar = CAGR / maximum reconstructed balance drawdown, not equity Calmar. The log-scale chart displays multiplicative growth; no intratrade equity series has been fabricated. All reported performance is before any commission missing from the export.

Year-by-year performance

2023 is the common failure year; 2026 is year-to-date, not a full year

Year	Trades	0.25 return	0.40 return	0.50 return	0.65 return
2020	251	39.25%	27.26%	24.88%	20.61%
2021	252	49.66%	36.53%	28.28%	33.54%
2022	256	57.90%	21.54%	12.23%	7.99%
2023	254	-16.75%	-17.85%	-6.67%	-2.04%
2024	258	66.26%	38.03%	35.95%	37.36%
2025	254	63.75%	37.70%	22.98%	15.19%
2026 YTD	172	67.95%	34.53%	30.22%	17.35%

All four variants are profitable in five of the six complete calendar years. In 2023, losses range from **-17.85% at 0.40** to **-2.04% at 0.65**. The 0.25 variant loses 16.75% despite its superior cumulative performance. A wider stop is not monotonically better: 0.40 is worse than 0.25 in that year.

The 0.25 run earns \$50,684.66 in 2026 YTD, or about 44.0% of its full-history cash profit. Compounding magnifies later dollar gains; this should not be interpreted as 44% of the underlying signal edge without normalizing by risk. Its 2020-2022 annual returns are also strong, so the strategy is not profitable solely because of 2026.

The wider 0.65 version improves resilience in 2023 and outperforms 0.50 in 2024: 37.36% versus 35.95%. Both 0.25 and 0.40 return more in that year. It does not lead every difficult subperiod, however: its 2025-2026 recovery episode is still long. These yearly observations are retrospective diagnostics, not out-of-sample evidence.

Returns use each calendar year's actual starting balance and all subsequent realized P&L, not net profit divided by the original \$10,000. There are no subsequent deposits/withdrawals to distort this calculation. January 2020 begins at report inception; September 2026 is incomplete.

Drawdown depth and recovery

A strategy can be profitable overall while keeping capital below its peak for 1-2 years

ATR	Balance DD	Peak date	Trough date	Recovery date	Days
0.25	33.07%	2023-01-06	2024-03-01	2024-07-11	552
0.40	30.60%	2023-01-06	2024-03-01	2024-11-06	670
0.50	17.84%	2023-01-06	2023-09-13	2024-05-23	503
0.65	12.00%	2023-01-06	2023-09-13	2024-03-06	425

For these four runs, the deepest relative balance drawdown is also the longest completed peak-to-recovery episode. All begin at the balance peak on **6 January 2023**. 0.25 and 0.40 bottom on 1 March 2024; the wider two bottom on 13 September 2023. The 0.40 run does not regain that peak until 6 November 2024.

Recovery duration deserves its own risk budget

0.65 has the lowest peak-to-trough loss, but its longest recovery is still **425 days**. Its next-longest episode runs from 5 June 2025 to 26 June 2026, **386 days**, with 11.78% closed-balance drawdown. Choosing the smoother stop does not eliminate prolonged stagnation.

The balance DD values here exclude floating losses between fills. MT5 reports larger equity DD: 33.57%, 31.11%, 18.77% and 13.11% respectively. The export has no tick-level equity path, so equity trough dates and intraday breach timing cannot be independently reconstructed. [1]

A live or funded-account decision needs both tolerable depth and tolerable time under water. Rules based on initial balance, trailing equity or daily loss must be simulated separately; these historical peak-to-trough numbers are not funded-account pass probabilities.

Monthly consistency

All 81 observed months are retained; September 2026 is partial

ATR	Positive months	Best month	Best return	Worst month	Worst return
0.25	48/81	2024-03	22.20%	2021-11	-10.52%
0.40	47/81	2021-02	16.33%	2024-02	-7.04%
0.50	48/81	2024-03	15.25%	2021-11	-6.89%
0.65	47/81	2024-07	11.88%	2022-02	-4.93%

Only **47-48 of 81 months** are positive: approximately 58%-59%. Even the lower-drawdown candidate therefore has many losing months. Smooth-looking long-term growth should not be confused with reliable monthly income.

The 0.25 version's best month is March 2024 (+22.20%) and its worst is November 2021 (-10.52%). The 0.65 version compresses these extremes: best July 2024 (+11.88%), worst February 2022 (-4.93%). This is a more concrete description of the trade-off than win rate alone.

Each heatmap cell is that specific year/month's compounded balance return; it is not pooled seasonality. Empty October-December 2026 cells are unavailable, not zero. The full numerical monthly comparison is in the appendix, and weekly/monthly CSVs accompany the audit data bundle.

Weekly behavior and rolling returns

ISO weeks run Monday-Sunday; first and final weeks are partial

ATR	Positive weeks	Best week return	Worst week return	Longest loss streak
0.25	191/350	14.73%	-5.01%	17
0.40	186/350	10.04%	-4.78%	9
0.50	195/350	8.67%	-4.71%	9
0.65	209/350	6.70%	-3.40%	9

0.25 has 191 positive weeks (54.6%) and a worst week of **-5.01%**, 6-12 February 2023. 0.65 has 209 positive weeks (59.7%) and a worst week of **-3.40%**, 4-10 September 2023. The 0.40/0.50 worst week is 4-10 April 2022, at -4.78%/-4.71%.

What the rolling chart adds

The trailing 252-weekday return turns weak or negative in the common drawdown period and strengthens later. This is consistent with a time-varying edge, not a stationary stream of identical trades. No single full-history PF describes every period adequately.

The largest observed one-trade loss is **-1.19% of starting balance** at 0.25, versus -1.12%, -1.05% and -1.00% for 0.40/0.50/0.65. A stop budget of 1% is not a guaranteed maximum realized loss. Fill prices relative to the submitted SL can explain losses beyond the planned amount; commissions would add further cost.

The 0.25 longest loss streak is 17; the other three show 9. These counts describe the submitted history only. A future losing streak can be longer. The audit bundle includes all 350 weekly rows per variant for examining specific adverse weeks.

Daily returns are based on settled/closed balance. Week/month returns compound the daily sequence; return attribution is by exit date. Every supplied trade closes the same day, avoiding an overnight mark-to-market ambiguity for this particular dataset.

Direction and time-of-day evidence

Both directions contribute; do not redesign the system from isolated subgroups

ATR	Long net USD	Short net USD	Long PF	Short PF	Long / short mean R
0.25	65,689.60	49,584.87	1.379	1.286	0.164 / 0.162
0.40	26,413.71	7,939.75	1.388	1.103	0.132 / 0.053
0.50	19,970.29	6,562.38	1.394	1.117	0.111 / 0.048
0.65	15,750.05	5,885.74	1.420	1.140	0.093 / 0.046

There are 887 longs and 810 shorts in every run. At 0.25, average budget-R is almost identical by direction: **0.164 long versus 0.162 short**. This contradicts a simple explanation that the strategy merely profited from holding long during a gold bull market. Wider-stop variants are more dependent on long-side contribution.

In 2023, long trades lose money in all four variants. At 0.50 and 0.65, shorts make a small cash profit while longs account for the net loss. In 2025, the wider three variants have losing shorts, while 0.25 shorts remain profitable. Long-only should therefore be a separately validated hypothesis, not an automatic repair.

Broker entry hour	Trades	0.25 mean R	0.40 mean R	0.50 mean R	0.65 mean R
6	700	0.159	0.104	0.089	0.073
7	341	0.243	0.128	0.112	0.105
8	245	0.294	0.161	0.142	0.112
9	185	-0.117	-0.091	-0.080	-0.048
10	99	0.160	0.080	0.081	0.055
11	49	0.059	0.145	0.141	0.124

75.8% of entries occur in hours 06-08. Hour 09 has 185 trades and negative average budget-R in all four runs. That is worth investigating against range size, volatility and direction, but filtering it out now would be a post-selection change. Hour 16 is also weak, with only 12 trades - far too little evidence for a confident rule.

Wednesday is the weakest weekday by mean budget-R in every variant (roughly +0.014 to +0.022), while Friday is strongest (+0.141 to +0.312). These are descriptive findings on data already examined. Do not stack weekday and hour filters on top of the range test in the same optimization batch.

Concentration and regime dependence

Cash concentration and risk-normalized concentration answer different questions

ATR	2024+ cash share	2024+ budget-R share	Top 10 cash share	Mean R after top 10 R removed
0.25	84.91%	58.19%	41.12%	0.117
0.40	78.61%	61.04%	36.77%	0.065
0.50	74.45%	58.69%	32.34%	0.057
0.65	67.47%	53.03%	27.88%	0.053

For 0.25, **84.9% of net cash profit** comes from 2024 onward. But that period contributes **58.2% of total budget-R**, from 40.3% of trades. Later performance is genuinely stronger, while compounding exaggerates the cash concentration. Both statements matter.

ATR	2020-2023 PF	2024-2026 PF	Early mean R	Later mean R
0.25	1.123	1.476	0.114	0.235
0.40	1.095	1.398	0.062	0.143
0.50	1.119	1.394	0.056	0.118
0.65	1.170	1.383	0.056	0.093

All four remain positive across the earlier 1,013 trades, which is a useful improvement over the screenshot-only evidence. However, early-period PF is only 1.095-1.170. The strategy has less room for additional cost or adverse execution in that segment than the full-history result suggests.

The ten largest cash winners account for 41.1% of 0.25 net profit, versus 27.9% at 0.65. Removing their recorded cash amounts leaves \$67,876.12 and \$15,604.68 respectively. These are **fixed-ledger subtraction exercises**, not recomputed equity curves after removing trades and resizing future orders.

Separately removing the ten largest budget-R outcomes leaves positive mean budget-R in every variant. That supports an edge broader than a handful of spectacular winners, while not proving robustness to entire weak regimes or future execution costs.

Portfolio implication

Calendar-aligned daily-return correlations span **0.817-0.955**: 0.25 versus 0.65 is 0.817; 0.50 versus 0.65 is 0.954. These configurations belong to one strategy family. Giving each a separate 1% allocation would concentrate essentially the same signal risk.

Costs, stop behavior and uncertainty

The exported commission and swap totals are zero in every run

The P&L identities reproduce a valuation of **\$100 per \$1 gold move per lot** throughout these particular reports. This is inferred and checked from fills, volume and P&L; it is not a universal contract assumption. Recorded bid/ask and execution effects may be embedded in prices. We cannot infer whether the zero commission reflects the intended live account or omitted tester charges.

ATR	Base PF	PF with +\$7/lot	PF with +\$27/lot	Net with +\$27/lot
0.25	1.333	1.316	1.271	97,175.56
0.40	1.237	1.223	1.184	27,351.01
0.50	1.248	1.234	1.196	21,435.34
0.65	1.272	1.258	1.219	17,836.62

Hypothetical incremental round-trip costs per recorded lot, not a quote from IC Markets. \$27 illustrates \$7 commission plus \$20 from an extra \$0.10 adverse move on each side at the inferred \$100 valuation. Volumes remain fixed at historical values; this is not a dynamic-resizing MT5 rerun. Base spreads must not be deducted twice.

ATR	SL exits	EOD exits	Avg hours held	Mean planned stop risk*
0.25	937	760	7.83	0.98%
0.40	640	1057	9.37	0.96%
0.50	462	1235	9.95	0.95%
0.65	280	1417	10.41	0.93%

Wider stops reduce SL exits from 937 to 280. All winners close at the scheduled 18:55 time; some EOD exits also lose. This explains the rising win rate without implying rising expectancy: a wider SL rescues some trades but reduces volume and the return from successful continuation days.

* Initial SL distance x filled volume x inferred \$100 valuation / pre-entry balance. The average drops below 1% because volume rounding matters. It is not the maximum realized loss.

Resampling is supportive, not live proof

A reproducible 2,000-sample circular moving-block bootstrap of weekday returns, using 10-day blocks and seed 17092026, gives positive 2.5th-97.5th percentile mean-return intervals in all four runs. For 0.25 the interval is +0.082% to +0.238% per weekday; for 0.65 it is +0.033% to +0.104%. These in-sample estimates assume a reusable historical distribution and do not correct for strategy selection, future regime changes or missing costs. They are not live success probabilities.

What to take forward

Keep the research narrow: validate the edge, then consider execution

Ranking after inspecting the full deals

0.25 remains the primary return candidate. It has the highest CAGR and average budget-R, both directions contribute, and its early-period result is positive. The cost stress remains positive, but the 33.57% reported equity DD and 552-day recovery rule out calling it low-risk at a 1% trade budget.

0.65 remains the primary lower-drawdown candidate. It handles 2023 best, has the best early-period PF and the smallest weekly/monthly losses. Its lower CAGR and multi-month stagnation are the price of that profile.

0.50 remains a control; 0.40 is lower priority. 0.40's extra return over 0.50 comes with much deeper DD and the longest recovery.

Next: nine range-filter runs, not a fresh broad search

For each stop: 0.25, 0.50, 0.65	Minimum range / D1 ATR	Maximum range / D1 ATR
A - exclude only very large ranges	0.00	0.80
B - tighter upper cap	0.00	0.60
C - also exclude tiny ranges	0.10	0.60

Keep percentage filtering off and all other inputs fixed. Compare each filtered result with its own unfiltered stop-matched baseline. These thresholds are proposed hypotheses, not estimated optimal values. The export does not contain range highs/lows or the exact frozen ATR, so the range-filter results cannot be simulated correctly from these deals alone. Run them in MT5 and export full reports.

Prefer improvement in net budget-R per calendar month, drawdown duration, realistic-cost performance and multiple years, rather than a smaller DD caused simply by taking fewer trades. Examine excluded versus retained days, especially 2023, without tailoring the rule only to that known failure year.

Before live deployment

Verify the actual account commission/spread model and broker DST policy, rerun with realistic costs and delay, preserve unseen data where available, and freeze one version for a 50-100 trade demo execution check. A later small live pilot might use 0.10%-0.25% risk only if validation passes and minimum-lot sizing allows it. That is a proposed cautious pilot, not approval to deploy now. Recheck any funded-account loss rules independently.

Methods, limitations and audit files

What was calculated, what was inferred, and what remains unknown

Measure	Definition / boundary
CAGR	$(\text{final balance} / 10,000)^{(365.25 / 2443)} - 1$, over reported bounds 1 Jan 2020 to 9 Sep 2026. No subsequent external cash flows.
Calendar return	Net P&L; / actual opening balance of the contiguous period; equivalent to compounding trade returns here. Last activity: 8 Sep 2026.
Budget-R	Trade net P&L; / (pre-entry account balance x 0.01). Keeps interpretation consistent despite lot rounding.
Drawdown duration	Elapsed calendar days from a realized balance peak to recovery of that peak. Unrecovered episodes end at the report boundary.
Daily statistics	Complete Monday-Friday calendar, including zero-trade days; 252 annualization; sample standard deviation; risk-free rate zero.
Trade accounting	Both-leg recorded commissions/swaps included; all happen to be zero. One position at a time, matched by symbol, direction, volume and order-linked SL.
Bootstrap	2,000 circular 10-weekday-block samples, full observed daily-series length, deterministic seed; confidence interval on mean daily return only.

Known limitations: exact tester tick-model selection, historical spreads and slippage settings are not fully specified in these reports; no independent price-feed audit was performed. Intratrade equity, MAE/MFE paths, rejected signals, range/ATR diagnostics and out-of-sample status remain unavailable. All previously reviewed periods are development evidence, even if subsequently split into years.

The supplied build prompt specifies a reusable dashboard, not a claim that a dashboard has been built. It requires proper handling of cash flows, partial closes, ambiguous hedging, date filters and unsupported metrics. For this report, the simpler one-entry/one-exit structure was verified rather than assumed.

Audit bundle

The accompanying ZIP contains normalized trade CSVs with source row references, daily balance/return CSVs, all monthly and weekly rows, correlations, analysis JSON and a methods note. These allow the reported numbers to be independently checked and provide clean comparison data for your future app. Side/exit-reason subgroup compounded values in the JSON are descriptive subset products, not independently backtested strategies.

Primary sources: ORBGOLD_025.xlsx, ORBGOLD_40.xlsx, ORBGOLD_050.xlsx and ORBGOLD_065.xlsx, Sheet1 Settings/Results/Orders/Deals. Inputs show both range filters false; only stop multiplier differs. These direct exports supersede screenshot-derived approximations for the overlapping runs.
